

## N<sub>2</sub>O Wastewater Sensor - A tool for Carbon Dosage Control

The N<sub>2</sub>O Wastewater Sensor makes it possible for you to measure nitrous oxide (N<sub>2</sub>O) emissions directly from individual wastewater treatment plants (WWTPs). With hundreds of installations worldwide, the sensor is established as a very durable process sensor requiring minimal maintenance. The data collected from sensor installations have been key to shaping mitigation strategies.

### N<sub>2</sub>O as a control parameter for carbon dosage

When the sensor is installed to monitor the N<sub>2</sub>O concentration in the liquid, you can use N<sub>2</sub>O as a control parameter for carbon dosage in the denitrification process. Nitrogen removal in wastewater is achieved through a combination of nitrification and denitrification as well as anammox (anaerobic ammonium oxidation). N<sub>2</sub>O is an obligate intermediate formed during denitrification. However, N<sub>2</sub>O is also formed during nitrification which is the main source of N<sub>2</sub>O emissions from WWTPs (Fig. 1).

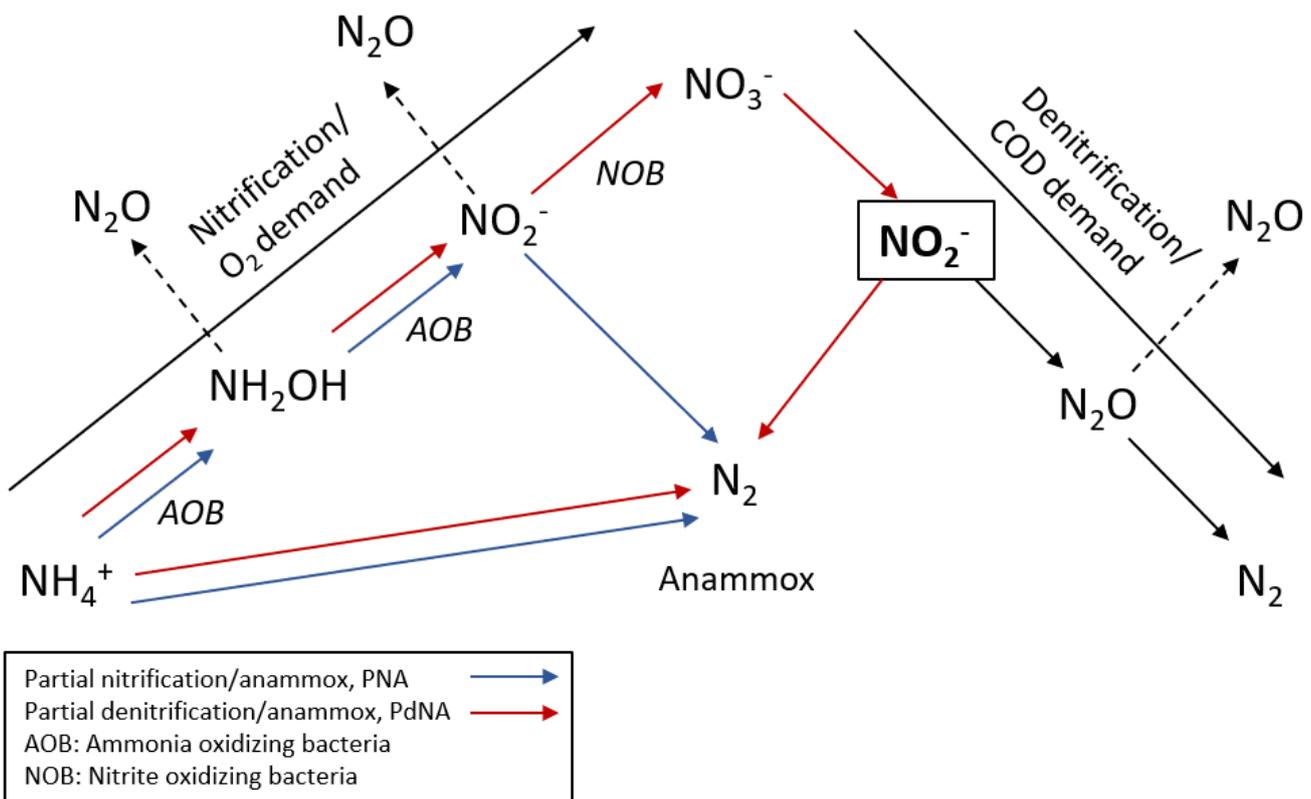

Fig. 1: N<sub>2</sub>O production pathways in WWTPs

### Measuring N<sub>2</sub>O yields important insights about all key substances

N<sub>2</sub>O formation is linked to the ammonium (NH<sub>4</sub><sup>+</sup>) loading, and N<sub>2</sub>O formation increases as the NH<sub>4</sub><sup>+</sup> turnover increases. If high NH<sub>4</sub><sup>+</sup> oxidation rates lead to NO<sub>2</sub><sup>-</sup> accumulation, N<sub>2</sub>O will build up in the liquid as a warning.

NO<sub>2</sub><sup>-</sup> is the key substrate, besides NH<sub>4</sub><sup>+</sup>, for anammox, but it is difficult to measure NO<sub>2</sub><sup>-</sup> with present sensors. The measurement will be indirect as NO<sub>2</sub><sup>-</sup> is formed and consumed inside biofilm or granules. Unlike NO<sub>2</sub><sup>-</sup>, N<sub>2</sub>O is not consumed by the anammox bacteria and therefore online N<sub>2</sub>O monitoring will provide a more precise measure of the substrate balance. Thus, N<sub>2</sub>O is tightly linked to NO<sub>2</sub><sup>-</sup> concentration through both nitrification and denitrification. This means that you can use the N<sub>2</sub>O sensor as a proxy for NO<sub>2</sub><sup>-</sup>.

### Carbon dosage can prevent excessive N<sub>2</sub>O emissions

Applied research has shown that a low COD/N ratio can lead to increased N<sub>2</sub>O production and that a COD/N ratio below 3.5 can lead to significant N<sub>2</sub>O emissions. Fig. 2 demonstrates the relationship between COD/N and N<sub>2</sub>O. The bell-shaped relationship between N<sub>2</sub>O and COD/N makes it possible to avoid excessive N<sub>2</sub>O emission by aiming for either a high (>3.5) or a low (<1) COD/N ratio (Fig. 2).

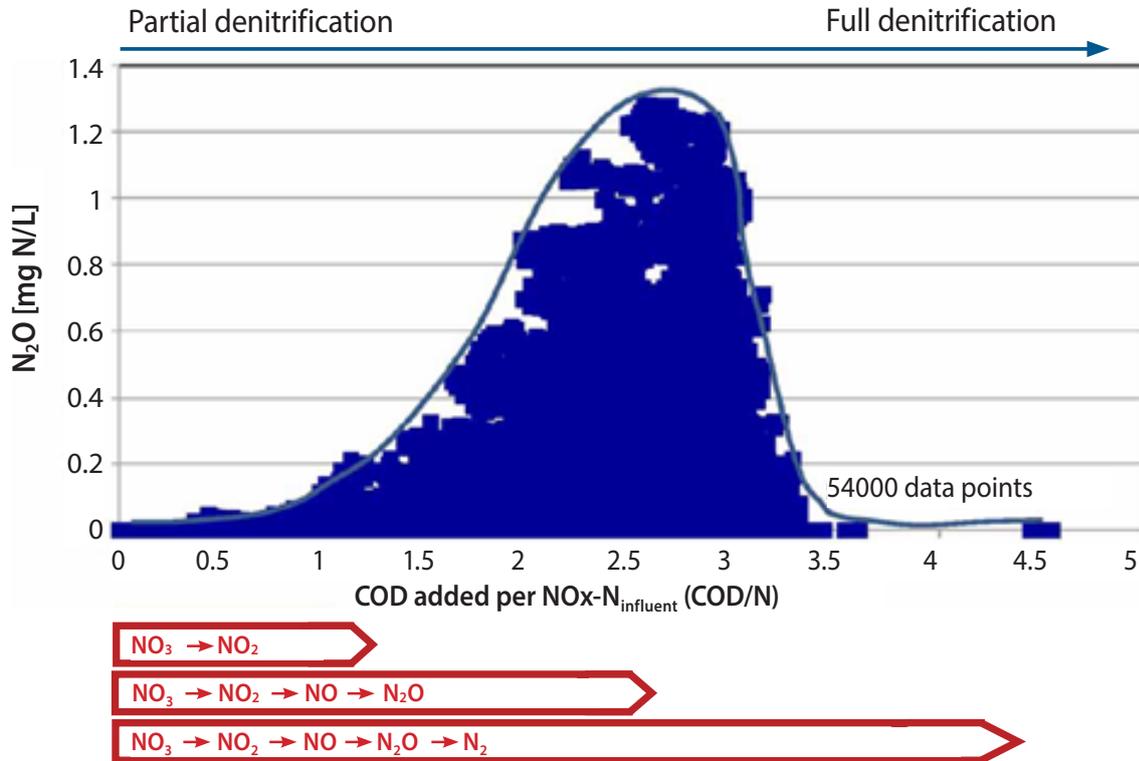

Fig. 2: Correlation between COD/N<sub>influent</sub> ratio and N<sub>2</sub>O concentration. Redrawn from Andalib et al. 2017.

From a process control standpoint, the slope of the N<sub>2</sub>O curve in response to the different COD/N-ratios can be used as an indicator for the dominating sludge process. If you aim for complete denitrification to N<sub>2</sub> to avoid N<sub>2</sub>O, you can apply the N<sub>2</sub>O sensor to monitor N<sub>2</sub>O concentration and increase the carbon load when the N<sub>2</sub>O concentration increases to ensure a COD/N ratio above 3.5.

### Anammox as an alternative

Anammox is an alternative nitrogen removal process where N<sub>2</sub> is formed from NH<sub>4</sub><sup>+</sup> and NO<sub>2</sub><sup>-</sup> (Fig. 1). Controlling the substrate availability is important for the successful implementation of anammox. Two substrate control strategies that have been suggested are PNA (Partial nitrification/anammox) and PdNA (Partial denitrification/anammox). The PNA process aims at partial nitrification by inhibiting NOB (nitrite-oxidizing bacteria) to increase the NO<sub>2</sub><sup>-</sup> available for anammox. However, the out-selection of NOB has proven operationally difficult. On the other hand, PdNA aims at partial denitrification to increase NO<sub>2</sub><sup>-</sup> availability (Fig. 1).

While it might appear as a detour, anammox is operationally easier to achieve. The process has been demonstrated at temperatures down to 20°C, which makes it relevant in many parts of the world during summer. In the PdNA case, the relationship between COD/N and N<sub>2</sub>O can be used for controlling the partial denitrification process to accumulate nitrite for anammox and keep the COD/N ratio below 1. The N<sub>2</sub>O sensor can monitor the N<sub>2</sub>O formation and decrease the carbon loading to achieve partial denitrification to NO<sub>2</sub><sup>-</sup>, which can be used for anammox. The carbon can then be harvested and used for biogas production.

### Avoid N<sub>2</sub>O emission and document your CO<sub>2</sub> footprint

In conclusion, you can use the N<sub>2</sub>O Wastewater Sensor as a tool for carbon dosage whether the aim is complete denitrification to avoid N<sub>2</sub>O emission or PdNA where the sensor is used as a proxy for NO<sub>2</sub><sup>-</sup>. Simultaneously, the new PdNA and PNA processes will make it possible for you to document their CO<sub>2</sub>-equivalent footprints in comparison to conventional activated sludge processes.
